I/O-efficient Topological Ordering of DAGs with Small Path Cover

Abstract:

I will present an $O(\text{sort}(m))$ -I/O algorithm for topologically sorting a directed acyclic graph (DAG) G with width $O(M/B)$, assuming that a chain decomposition of G is given. Here M and B are the number of elements that fit in internal memory and a block, respectively, m is the number of edges in the DAG, and $\text{sort}(m)$ denotes the I/O complexity of sorting m data items. I will then show that this result can be generalized to all DAGs and the assumption can be relaxed to obtaining a vertex-disjoint path cover of an acyclic supergraph of G consisting of $O(M/B)$ directed paths.

For some classes of DAGs, such a path cover can be obtained in $O(\text{sort}(m) \text{ polylog}(m))$ I/Os, thereby obtaining a topological sorting algorithm of the same complexity for these graph classes.
